

## **Veterans Institutional Exposure Initiative (VIEI)**

### **Modernizing VA Disability Claims: Replacing First-Level Checklist Reviews with AI-Driven Medical Analysis**

#### **Executive Summary**

The first decision made on a VA disability claim often determines its entire trajectory. Yet today, that decision is largely procedural, checklist-based, and performed by generalist personnel without medical training. This structure systematically disadvantages veterans whose conditions involve latency, cumulative exposure, or delayed diagnosis.

VIEI proposes replacing the initial review stage with an AI-driven medical and regulatory assessment, supported by human oversight, to ensure claims are evaluated against modern medical science rather than administrative shortcuts.

#### **Institutional Exposure and Systemic Failure**

Many service-connected illnesses—particularly those related to tobacco use, environmental hazards, industrial exposures, and occupational risk—do not manifest until decades after military service. Current first-level reviews are not equipped to evaluate these realities.

Claims are frequently denied due to lack of in-service treatment records, despite well-documented medical evidence that delayed onset is expected for many exposure-related diseases.

#### **Case Pattern: Delayed-Onset Respiratory Disease**

Veterans with emphysema and similar respiratory conditions are often denied because there is no record of diagnosis or treatment during service. Medical science establishes that such diseases may take 20–30 years to become clinically detectable. Absence of in-service treatment is therefore expected, not disqualifying.

#### **Why AI Belongs at the First Review Stage**

An AI-based first-level review system would provide medical knowledge at scale, consistent application of regulations, and objective analysis free from fatigue or workload bias. AI can recognize latency patterns, correlate exposure histories, and flag cases requiring escalation to medical professionals.

#### **Skill Gaps, Appeals Burden, and the Role of AI Escalation**

A frequent cause of initial claim denial is not the absence of merit, but the absence of the specialized medical skill sets required to make fully objective, evidence-based determinations. When complex conditions involving delayed onset, cumulative exposure, or evolving medical understanding are evaluated using administrative checklists alone, claims

are more likely to be disapproved prematurely.

As a result, veterans are routinely forced into prolonged appeals processes to correct errors that could have been avoided at the first decision point. This increases emotional strain on veterans, lengthens time to benefits, and contributes significantly to the VA appeals backlog.

The use of AI at the first review stage would not eliminate the human factor. On the contrary, it would strengthen it. AI systems can be designed to automatically flag and escalate claims involving complex medical questions to personnel with appropriate clinical expertise. This ensures that human judgment is applied precisely where it adds the most value—rather than after years of unnecessary appeals.

### **Workforce Considerations**

This proposal is not a criticism of GS-level reviewers, who perform their duties as trained. The failure lies in system design, not personnel. AI would reduce preventable denials, lower appeal volumes, and allow human reviewers to focus on oversight, quality assurance, and veteran engagement.

### **Conclusion**

Veterans should not be required to navigate years of appeals to overcome decisions that contradict established medical knowledge. Replacing checklist-driven initial reviews with AI-based medical analysis is a practical, cost-effective reform that aligns the VA disability system with scientific reality.
